

EQ in the optical module

Overview

In the optical domain, an equalizer is a device that equalizes the gain response over a particular wavelength range. Feed-Forward Equalization (FFE) is one of the most critical technologies used in high-speed digital communication systems, especially in optical transceivers, SerDes interfaces, and backplane/high-speed copper links. These settings are essential for optimizing signal integrity and minimizing bit error rate (BER) in high-speed data center networks. 3 illustrates the concept of. The present application provides an optical equalizer, an optical module, an optical chip, and an optical communication device, for use in implementing a splitting and coefficient integrated amplitude-type optical equalizer and implementing an optical equalizer having smaller insertion loss. Operating at the physical layer of the OSI model, optical modules are core devices in optical. Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is.
