

The working principle of the beam splitter in the low-voltage well

Overview

The behavior of the beam splitter is core to the presence and reduction of noise due to vacuum fluctuations in LIGO, which injects a squeezed vacuum state into the empty input port of the beamsplitter to reduce coupling of quantum noise into the interferometer. A beam splitter or beamsplitter is an optical device that splits a beam of light into a transmitted and a reflected beam. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. Beamsplitters are often classified according to their construction: cube or plate. Cube Beam Splitter: Cube beam splitters are built by stacking two triangular glass prisms and bonding them with epoxy or urethane resins. The resin layer's thickness can be changed to regulate the power-splitting ratio for certain wavelengths. Moreover, thin metal or dielectric coatings can be.
